## Abstract

1        In this project we trained autonomous driving agents in simulation, that are to  
2        be tested later on real hardware as well. For the simulation we used the Gym-  
3        Duckietown Simulator -provided by the official Duckietown project. Several  
4        navigation challenges exist, this time we focused on LF, hence we only had to  
5        follow curves, no intersections or extra obstacles were present.

## 6    1 INTRODUCTION

7        Duckietown is a modular robotics and AI ecosystem. It provides hardware, software, simulation,  
8        datasets and learning materials to encourage both teaching and learning.

### 9    1.1 Simulator

10       One of the most important parts of the ecosystem is the Gym-Duckietown Simulator, which  
11       provides a physically realistic environment. It is compatible with real world, so the algorithms  
12       developed in simulation can be tested on real hardware and maps as well. In the simulation you can  
13       easily generate agents (Duckiebots), cities, streets, obstacles, intersections, etc. The fact that this  
14       simulator is also integrated with the OpenAI Gym environment, makes reinforcement learning much  
15       easier.

## 16   2 TRAINING

### 17   2.1 Reinforcement Learning

18   ...TODO...

### 19   2.2 RAY

20       Ray provides a simple, universal API for building distributed applications. It is packaged with other  
21       libraries for accelerating machine learning workloads, of which we used RLlib and Tune. ...TODO...

#### 22   2.2.1 RLlib

23       RLlib is the industry-standard reinforcement learning Python framework built on Ray. It offers both  
24       high scalability and a unified API for a variety of applications. ...TODO...

### 25 **2.2.2 Tune**

26 Tune is a Python library for experiment execution and hyperparameter tuning at any scale. ...TODO...

### 27 **2.2.3 PPO**

28 RLLib comes with built-in NN models (that can be customized), but an algorithm for the training had  
29 to be chosen. Based on comparisons, we opted for Proximal Policy Optimization (PPO). ...TODO...

## 30 **2.3 Hyperparam optimization**

31 ...TODO...

## 32 **2.4 Tensorboard logs**

33 ...TODO...

## 34 **3 TESTING**

35 The trained model can be easily tested with the help of the Simulator. Given any observation  
36 (image), the trained agent can compute the best action from the action space. In our case we need 2  
37 values - velocity of left and right motors. Then the environment's step function can be called with the  
38 computed action passed as an argument. As the action is executed, the environment returns the next  
39 observation and this process continues.. The environment's render function makes the self-driving  
40 agent visible.

## 41 **4 WRAPPERS**

42 Wrappers are quite important, since they allow us to add functionality to environments - modify  
43 rewards, observations etc. We used the original gym-duckietown wrappers with slight modifications  
44 for basic observation processing, like image resizing or normalizing. In addition, we prepared 2  
45 custom wrappers.

### 46 **4.1 CropWrapper**

47 This wrapper is used during the observation phase in order to mitigate the processing of the  
48 unnecessary data parts such as the sky and the two sides of the camera view. In this project, we used  
49 a custom script, that makes it easy to manipulate the crop ratio for the processed image. This is done  
50 by using an additional argument, the crop parameter, which basically means the proportion of the  
51 cropped size relative to the whole size of that specific side.

### 52 **4.2 DtRewardWrapper**

53 The rewarding concept is one of the most important parts of the Reinforcement Learning  
54 framework, as the agents' performance is highly relied on it. The reason for this, is that it is the only  
55 (scalar) feedback from the environment which the agent receives and later uses to understand the  
56 inner dynamics, which is basically the core of the learning process. As a result, the right choice of  
57 rewarding concept can improve the success of the training and thus the performance of the trained  
58 agent (model).

59 One of the concepts most commonly used in literature is based on the distance between the lane  
60 center line and the agent, but due to the fact, that in our case through the actions we not only  
61 manipulate the position of the agent, but also influence the speed. Therefore we had to formulate the  
62 reward to be able to control the agent's speed and the position through the rewarding concept.

63

64 **5 DEVELOPMENT ENVIRONMENT**

65 **5.1 Linux VM**

66 ...TODO...

67 **5.2 Docker**

68 ...TODO...

69 **6 CONCLUSION**

70 ...TODO...
